

PEST CONTROL DEVICE AND METHOD

Abstract of the Disclosure

An apparatus and method for detecting and/or  
controlling subterranean termites. A station at least  
5 partially receivable within a cavity has at least one  
opening therein to provide access by the termites to an  
interior volume of the station. The apparatus also  
includes an aggregation base attractive to the termites  
received within the interior volume of the station. The  
10 aggregation base includes at least one void for forming an  
aggregation site for the termites. The apparatus further  
includes a replaceable container received within the  
interior volume of the station and positioned adjacent the  
aggregation base. The container has at least one opening  
15 in a surface thereof facing the aggregation base to permit  
the passage of termites from the aggregation base to an  
interior chamber of the container. The container is sized  
and shaped such that the container may be removed from the  
station with minimal disturbance to the aggregation base,  
20 thereby preserving any aggregation site formed by the  
termites within the void of the aggregation base.
